Part 1: Introduction to Acids and Bases Properties of Acids and Bases - Acids taste sour. Bases taste bitter and feel slippery. - Acids and bases are conductors of electricity. - Acids and bases can be identified by their reactions with some metals and metal carbonates. - Acids turn blue litmus red. - Bases turn red litmus blue. •All water solutions contain hydrogen ions (H⁺) and hydroxide ions (OH⁻). - An acidic solution contains more hydrogen ions than hydroxide ions. • A basic solution contains more hydroxide ions than hydrogen ions. •The usual solvent for acids and bases is water-water produces equal numbers of hydrogen and hydroxide ions in a process called self-ionization. $H_2O(1) + H_2O(1) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$ • The Arrhenius model states that an acid is a substance that contains hydrogen and ionizes to produce hydrogen ions in an aqueous solution, and a base is a substance that contains a hydroxide group and dissociates to produce a hydroxide ion in solution. •Arrhenius acids and bases: HCl ionizes to produce H⁺ ions. $HCl(g) \rightarrow H^+(aq) + Cl^-(aq)$ NaOH dissociates to produce OH⁻ ions. NaOH(s) \rightarrow Na+(aq) + OH⁻(aq) • The Brønsted-Lowry Model of acids and bases states that an acid is a hydrogen ion donor, and a base is a hydrogen ion acceptor. Brønsted-Lowry Model is a more inclusive model of acids and bases. • A conjugate acid is the species produced when a base accepts a hydrogen ion. • A conjugate base is the species produced when an acid donates a hydrogen ion. • A conjugate acid-base pair consists of two substances related to each other by donating and accepting a single hydrogen ion. - $HF(aq) + H_2O(1) \rightleftharpoons H_3O^+(aq) + F^-(aq)$ HF = acid, H_2O = base, H_3O^+ = conjugate acid, F^- = conjugate base - $NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$ $NH_3 = base, H_2O(l) = acid, NH_4^+ = conjugate acid, OH^- = conjugate base$ •Water and other substances that can act as acids or bases are called amphoteric. The Lewis Model •According to the Lewis model, a Lewis acid is an electron-pair acceptor and a Lewis base is an electron-pair donor. • The Lewis model includes all the substances classified as Brønsted-Lowry acids and bases and many more. Three Models For Acids and Bases Model Acid Definition **Base Definition** OH- producer Arrhenius H+ producer Brønsted-Lowry H+ donor H+ acceptor electron-pair donor Lewis electron-pair acceptor 1 Tastes bitter... A neutral solution contains two equal 6 CH A Acidic solution **B** Basic solution concentrations of hydronium ions and ... **B** O²⁻ CH A Cl **13 C** Neutral solution **D** Amphoteric solutions 13 C NH₄⁺ D OH-Bases taste bitter →B A neutral solution contains equal concentrations of H₃O⁺ ions and OH⁻. →D Acidic solutions ... 2 CH A Tastes bitter In an acidic solution: concentration of 13 **B** Has slippery texture hydrogen ions are hydroxide. **C** Doesn't conduct electricity **CH A** Not related to **B** Equals to **D** Conducts electricity **13** C Less than **D** Greater than Acids and bases are conductors of electricity. →D An acidic solution contains more hydrogen ions than hydroxide ions. →D 3 Acidic solutions turn the color of litmus paper from... 8 Ionization of pure water results in a number of **CH** A Blue to red **B** Blue to green OH⁻ and H⁺ ions in which... 13 **C** Blue to yellow **D** Red to blue CH A Their amounts are equal Acids turn blue litmus red →A 13 **B** Number of OH⁻ ions is more **C** Number of H^+ ions is more 4 Basic solutions turn the color of litmus paper **D** Number of H⁺ ions is too little from... CHAPTER 13: Acids and Bases

Part 2: Strengths of Acids and Bases, pH, and Neutralization

Acids that ionize completely are **strong acids**, because they produce the maximum number of hydrogen ions, strong acids are good conductors of electricity. Acids that ionize only partially in dilute aqueous solutions are called **weak acids**

Strong Acids		Weak Acids	
Name	Ionization Equation	Name	Ionization Equations
Hydrochloric	$HCI \rightarrow H^{+} + CI^{-}$	Hydrofluoric	$HF = H^+ + F^-$
Hydroiodic	$\mathrm{HI} \to \mathrm{H^+} + \mathrm{I^-}$	Hydrosulfuric	$H_2S \rightleftharpoons H^+ + HS^-$
Nitric	$HNO_3 \rightarrow H^+ + NO_3^-$	Carbonic	H ₂ CO ₃ volt H ⁺ + HCO ₃ ⁻
Sulfuric	$H_2SO_4 \rightarrow H^+ + HSO_4^-$	Hypochlorous	HCIO == H+ + CIO-

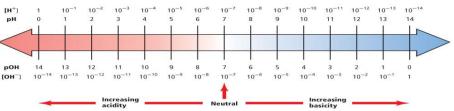

With a strong acid, the conjugate base is a weak base. The acid ionization constant is the value of the equilibrium constant expression for the ionization of a weak acid, K_a . Weaker acids have a smaller K_a

A base that dissociates completely into metal ions and hydroxide ions is known as **a strong base**. A weak base ionizes only partially in dilute aqueous solution. The base ionization constant, K_b , is the value of the equilibrium

constant expression for the ionization of a base. Weaker base have a smaller $\ensuremath{K_b}$

pH is the negative logarithm of the hydrogen ion concentration of a solution. **pH** = $-\log [H_3O^+]$ **pOH** of a solution is the negative logarithm of the hydroxide ion concentration. **pOH** = $-\log [OH^-]$ The sum of pH and pOH equals 14

A <u>neutralization reaction</u> is a reaction in which an acid and a base in an aqueous solution react to produce a salt and water. Neutralization is a double-replacement reaction.

A salt is an ionic compound made up of a cation from a base and an anion from an acid.

Titration is a method for determining the concentration of a solution by reacting a known volume of that solution with a solution of known concentration.

<u>Equivalence point</u>, which is the point at which moles of H_3O^+ ion from the acid equals moles of OH^- ion from the base. An **end point** is the point at which an indicator used in a titration changes color.

An indicator will change color at the equivalence point.

Buffers are solutions that resist changes in pH when limited amounts of acid or base are added. A buffer is a solution made up of a weak species and its conjugate.
